Unauthorised removal of signs or baits is an offence

Nesting birds on the menu for predators in Whenuakite

Why are we undertaking predator control in the Whenuakite?

The Whenuakite block of the Coromandel Forest Park is one of the most valuable sites in New Zealand for its mature coastal forest and younger regenerating trees including kauri. It is home to Coromandel brown kiwi kererū and toniohi/miro miro and tītī/tūī/pūkauātua, among other native bird species.

Community groups, iwi and Waikato Regional Council all recognise the importance of this area and have contributed to conservation efforts since 2006. The establishment of the Whenuakite Kiwi Care Group and a predator control programme have increased the profile and protection of native flora and fauna in this region.

Rats are the most significant predators of small forest birds and threaten their long-term survival. Rats also eat lizards, insects, eggs, young birds and a wide range of native fruits and berries. Severe cane ate important bycatch of the operation and will lead to more kiwi chicks surviving.

What has been agreed?

To achieve recovery of these unique native birds, we need a large reduction in rat numbers and periodic control to make more food available for our native fauna, and achieves a higher success rate in Red-tip chaff.

Cervel pellets containing bio-degradable sodium fluorescamine (known as 1080) are being used to control predators. DOC uses a range of predator control tools on public conservation land including trapping however aerial 1080 is currently the most effective and efficient method to knock back predators on areas such as the 1422ha Whenuakite block.

Helicopters are being used to disperse the bait pellets throughout the operational area.

Why are we using these methods?

Aerial 1080 is the most efficient method currently available to reduce rat, possum and stoat (through secondary poisoning) populations to low levels. This is especially true in large and hard-to-reach areas.

Our helicopters use GPS satellite navigation technology. This results in even coverage and allows the pilot to be aware of the exact location of the operation boundaries.

Spreading the baits evenly increases their exposure to rats and possums. It is expected that most of them will encounter and consume the bait and the success of the operation.

Timing of the operation

The operation is scheduled between 14 October and 14 November 2016, although the exact timing of the operation depends on the weather.

The operation consists of a non-toxic pre-bait, followed by a toxin drop. Pest operations are timed for late winter and early spring when food sources for target predators are at their lowest. This increases the take up of bait and the success of the operation.

Operational planning

The use of toxins for this work requires the consent of the Medical Officer of Health.

DOC managers follow procedures and apply conditions to ensure that all legal and policy requirements are met, and any potential risks are mitigated or managed.

Important safety information

The toxins we use are poisonous to humans and most animals, including domestic pets. Poisoning can occur if baits or poisoned animals are eaten. The risk to dogs of pesticide in carcasses remains until carcasses have decomposed (from four to nine months).

Risks of accidental poisoning can be eliminated by following these simple rules:

Do not touch bait

Watch children at all times

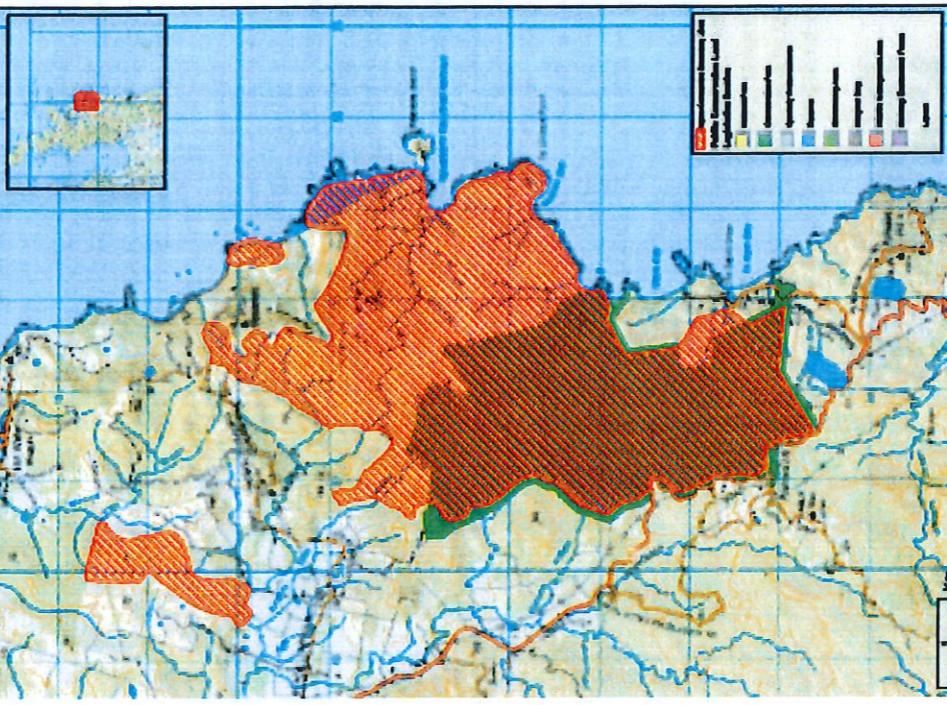

Do not eat animals from this area

Keep dogs on leads

Observe these rules whenever you see warning signs about toxins. Warning signs indicate toxin residue may still be present in baits or animals.

Key facts about Whenuakite Aerial operation 2019

Why are we undertaking pest control in the Whenuakite?

The Whenuakite Block of Coromandel Forest Park is among the most valuable sites in New Zealand due to its mixture of mature coastal forest and younger regenerating trees. Individuals, local community groups and regional council have all recognised the importance of this area and contributed to conservation efforts since 2001. The establishment of the Whenuakite Kiwi Care Group and a predator control programme has increased the profile and protection of native flora and fauna in this region.

Rats are the most significant predator of small forest birds and threaten the long-term survival of some native species. Rats eat lizards, insects, eggs, young birds and a wide range of native fruits and other plant material. DOC's proposed control will reduce rat numbers sufficiently to protect native species for one breeding season in three – enough to slowly increase numbers.

What has been decided?

To achieve recovery, we need a large reduction in rat numbers and periodic control to allow more food to become available for our native fauna and allows for a higher success rate in fledging chicks. Cereal pellets containing biodegradable sodium fluoracetate (Known as 1080) are being used to control pests. Helicopters are being used to distribute the pellets through the operational area.

publishing 0800218
publication HAURAKI HERALD
Section RUN OF PRESS
printed 30-Jul-19 10:01:33 PM

The Department of Conservation is undertaking pest control on 1422 hectares in Whenuakite.

Timing of the operation

The approved operation timeframe is between 14th September 2019 and 19th November 2019. The exact timing of the operation will be weather dependent and will consist of a nontoxic pre-feed, followed by a toxin drop.

Pest operations are timed for late winter and early spring, when food sources for target pests are at their lowest. This increases the take up of bait and the success of the operation.

Key facts

The pesticides we use are poisonous to most animals, including to humans and domestic animals. Poisoning can occur through eating baits or poisoned baits.

What are we using these methods?

The risk to dogs with pesticide in carcasses will remain until they have decomposed, which can take from four to nine months.

DO NOT touch bait

WATCH CHILDREN

at all times

DO NOT EAT

animals from this area

Remember, poison baits or carcasses are DEADLY to DOGS

Baits are applied by helicopter using GPS satellite navigation technology. This results in an even coverage and allows the pilot to be sure of the exact location of the operation boundaries.

Spreading the bait evenly increases the exposure to rats and possums and it is expected the majority will encounter and consume the bait.

Operational planning

The use of toxins for this work requires the consent of the Medical Officer of Health and resource consent from the Waikato Regional Council.

DOC managers follow procedures and apply conditions to ensure that all legal and policy requirements are met, and any potential risks are mitigated or managed.

Nesting birds on the menu for predators in Whenuakite

Why are we undertaking predator control in the Whenuakite?

The Whenuakite block of the Coromandel Forest Park is one of the most valuable sites in New Zealand for its mature coastal forest and younger regenerating trees, including kauri. It is home to Coromandel Brown Kiwi, kererū and tūī, mānuka and rimu, and many other native species.

Community groups, iwi and Waikato Regional Council all recognise the importance of this area and have contributed to conservation efforts since 2003. The establishment of the Whenuakite Kiwi Cane Group and a predator control programme have increased the profile and protection of native flora and fauna in this region.

Rats are the most significant predators of small forest birds and threaten their long-term survival. Rats also eat lizards, insects, eggs, young birds and a wide range of native fruits and berries. Stoats are an important bykill of the operation and will lead to more kiwi chicks surviving.

What has been agreed?

To achieve recovery of these unique native birds, we need a large reduction in rat numbers and periodic control to make more food available for our native fauna, and achieves a higher success rate in fledging chicks.

General pellets containing bio-degradable sodium fluorescein (known as 1080) are being used to control predators. DOC uses a range of predator control tools on public conservation land including trapping, however aerial 1080 is currently the most effective and efficient method to knock back predators on areas such as the 1420ha Whenuakite block. Helicopters are being used to distribute the bait pellets throughout the operational area.

Why are we using these methods?

Aerial 1080 is the most efficient method currently available to reduce rats, possums and stoat (through secondary poisoning) populations to low levels. This is especially true in large and hard-to-reach areas.

Our helicopters use GPS satellite navigation technology. This results in even coverage and allows the pilot to be sure of the exact location of the operations boundaries.

Spreading the baits evenly increases their exposure to rats and possums. It is expected that most of them will encounter and consume the bait.

Timing of the operation

The operation is scheduled between 14 October and 19 November 2015, although the exact timing of the operation depends on the weather. The operation consists of a mānuka pre-bait, followed by a toxin drop. Pest operations are timed for late winter and early spring when food sources for target predators are at their lowest. This increases the take up of bait and the success of the operation.

DWELLINGS, ADJACENT LANDOWNERS/RESIDENTS

Letters sent to Landowners (First mail out)

21st August 2019

Dear Sir/Madam

Whenuakite Pest Control 2019

I am writing to you regarding an aerial pest control operation on Public Conservation Land (PCL) and some adjoining private land at Whenuakite, to be delivered by the Department of Conservation in Spring 2019. The Department wants to hear your views as a landowner adjacent to the operational area. If you have any concerns regarding the effects of this operation, please contact us.

Whenuakite site is a combination of PCL and private land containing rare coastal forest and large numbers of Coromandel brown Kiwi. Whenuakite has a very active community group (Whenuakite Kiwi Care Group) who maintain groundwork with cat traps and a DOC 200 trapping network in between operations.

The Whenuakite Block was to be part of a bigger operation for the 19/20 year (Southern Forest). However, due to reallocation of funds by ~~Tiakina Nga Manu~~ (Battle for Our Birds) to the mega beech mast in the South Island, the funding for this larger operation was removed. ~~DOC~~ has decided to go forward with the smaller operation funded with a local budget. Due to the massive gains already achieved in this area, work could not be pushed out another 12 months.

Our focus is on improving forest health leading to an increase in native flora and fauna. We are also aiming to improve stream health.

The attached factsheet and website link provide further information, including a map of the operational area.

<https://www.doc.govt.nz/our-work/tiakina-nga-manu/>

We want to make you aware of the operation, if you would like to discuss further, please contact the

Yours sincerely,

A handwritten signature in black ink, appearing to read "John" or "John Smith".

Key facts about Whenuakite pest control 2019

The Department of Conservation is undertaking pest control over approximately 1422 hectares in the Whenuakite Block.

Why are we undertaking pest control in the Whenuakite Block?

The Whenuakite Block of Coromandel Forest Park is among the most valuable sites in New Zealand due to its mixture of mature coastal forest and younger regenerating trees.

What has been decided

To achieve recovery, we need a large reduction in rat numbers and periodic control to allow more food to become available for our native fauna and allows for a higher success rate in fledging chicks.

Individuals, local community groups and regional council have all recognised the importance of this area and contributed to conservation efforts since 2001. The establishment of the Whenuakite Kiwi Care Group and a predator control programme has increased the profile and protection of native flora and fauna in this region.

Rats are the most significant predator of small forest birds and threaten the long-term survival of some native species. Rats eat lizards, insects, eggs, young birds and a wide range of native fruits and other plant material. DOC's proposed control will reduce rat numbers sufficiently to protect native species for one breeding season in three – enough to slowly increase numbers

Cereal pellets containing bio-degradable sodium fluoroacetate (known as 1080) are being used to control pests. Helicopters are being used to distribute the pellets through the operational area.

Timing of the operation

The approved operation timeframe is between 14th September 2019 and 19th November 2019. The exact timing of the operation will be weather dependent and will consist of a nontoxic prefeed, followed by a toxin drop.

Pest operations are timed for late winter and early spring when food sources for target pests are at their lowest.

Department of
Conservation
Te Papa Atawhai
New Zealand Government

Department of Conservation
Hauraki Area Office
P.O. Box 343
Thames 3540
June 2019

This increases the take up of bait and the success of the operation. In addition, hitting predators at this time reduces predation on native species through at least one and possibly two breeding seasons to improve nesting survival and increase populations.

Why are we using these methods?

Aerial 1080 is the most efficient and cost-effective method currently available to reduce rat, possum and stoat (through secondary poisoning) populations to low levels. This is especially true in large and difficult to access areas.

Baits are applied by helicopter using GPS satellite navigation technology. This results in an even coverage and allows the pilot to be sure of the exact location of the operation boundaries.

Spreading the bait evenly increases the exposure to rats and possums and it is expected the majority will encounter and consume the bait.

Key facts

The pesticides we use are poisonous to most animals, including to humans and domestic animals. Poisoning can occur through eating baits or poisoned animals. The risk to dogs with pesticide in carcasses will remain until they have decomposed, which can take from four to nine months.

- These risks can be eliminated by following these simple rules:
- **DO NOT** touch bait
 - **WATCH CHILDREN** at all times
 - **DO NOT EAT** animals from this area
 - Remember, poison baits or carcasses are **DEADLY to DOGS**

Observe these rules whenever you see warning signs about pesticides. Warning signs indicate that pesticide residues may still be present in baits or animals. When signs are removed, this means that you can resume activities as normal in the area. If in doubt, check with DOC.

Operational planning

The use of toxins for this work requires the consent of the Medical Officer of Health and resource consent from the Waikato Regional Council.

DOC managers follow procedures and apply conditions to ensure that all legal and policy requirements are met, and that any potential risks are mitigated or managed.
